Finding that the $\Lambda(1405)$ consist of $\bar{K}N$ bound state with only a small admixture of elementary threequark state suggests a reasonable model is possible with the \bar{K} , N , Σ , and π as elementary particles interacting via potentials or meson-exchange. The work is to work out potentials which would reproduce the low-energy $\bar{K}N$ scattering data, kaonic hydrogen atom data, and transition amplitudes predicted by other theoretical approaches. Unlike interactions in momentum space derived in the framework of quantum field theory, such a potential would be conveniently applied to multi-particle systems. The computational result shows the feasibility of the coupled-channel interations.
